DOE-0173-94 DOE-FN/EPA 30 RESPONSES

Department of Energy

Fernald Environmental Management Project

OCT 2 6 1993

_ 3 3 2

DOE-0173-94

Mr. James A. Saric, Remedial Project Director U.S. Environmental Protection Agency Region V - 5HRE-8J 77 W. Jackson Boulevard Chicago, Illinois 60604-3590

Mr. Graham E. Mitchell, Project Manager Ohio Environmental Protection Agency 40 South Main Street Dayton, Ohio 45402-2086

Dear Mr. Saric and Mr. Mitchell:

TRANSMITTAL OF RESPONSE TO RISK ASSESSMENT COMMENTS ON THE REPORT "CHARACTERIZATION OF BACKGROUND WATER QUALITY FOR STREAMS AND GROUNDWATER"

References: 1) Letter, J.A. Saric to J.R. Craig, "Conditional Approval of Characterization of Background for Streams and Groundwater," dated June 10, 1993

2) Letter, J.R. Craig to J.A. Saric, "Transmittal of Response to Comments on the Report Characterization of Background Water Quality for Streams and Groundwater," dated August 31, 1993

Enclosed are responses to the United States Environmental Protection Agency (U.S. EPA) risk assessment comments on the report, Characterization of Background Water Quality for Streams and Groundwater (Reference 1). As explained in Reference 2, the Department of Energy, Fernald Field Office (DOE-FN) is responding to the U.S. EPA's two comments on risk assessment separately because the comments raise issues which go beyond the scope of the Background report.

The Background report will be revised at a later date once data from additional sampling of locations W1 (background location on the Great Miami River) and W5 (background location on Paddys Run) become available and the responses to U.S. EPA and Ohio Environmental Protection Agency (OEPA) comments are finalized.

If you or your staff have any questions, please contact Kathi Nickel at (513) 648-3107.

Sincerely

FN:Nickel

Jack R. Craig

RESPONSE TO U.S. EPA RISK ASSESSMENT COMMENTS CHARACTERIZATION OF BACKGROUND WATER QUALITY FOR STREAMS AND GROUNDWATER REPORT MAY 1993

RISK ASSESSMENT ISSUES

1

Comment: At FEMP, there is a risk assessment issue regarding filtered and unfiltered metals analyses for groundwater. All metals analyses were conducted on filtered samples, including groundwater samples from private wells. Private wells are being used to calculate background levels in the glacial overburden and the Great Miami Aquifer. Using filtered versus unfiltered samples is probably of less concern in monitoring wells installed in the Great Miami Aquifer, because the wells were developed using a relatively low turbidity requirement. However, the issue is of greater concern for monitoring wells in the glacial overburden, where the turbidity requirement could not be reached, and for private wells in the glacial till and Great Miami Aquifer, which were installed without regard to turbidity.

A 0.45 micron (μ m) membrane filter size was used to filter groundwater samples. According to the U.S. Environmental Protection Agency's Risk Assessment Guidance for Superfund, Volume 1, Human Health Evaluation Manual (Part A), dated December 1989, a 0.45- μ m filter may screen out some potentially mobile particulates to which contaminants are absorbed, thus underrepresenting contaminant concentrations (see Page 4-13 of the guidance). The guidance suggests the use of a 1.0 μ m-filter. In addition, the guidance states that if unfiltered water is of potable quality, data from unfiltered water samples should be used to estimate exposure (see Page 4-13 and 6-27 of the guidance).

Two options exist to overcome this potential problem: (1) collect one round of groundwater samples from all background wells and other selected wells, analyze unfiltered samples for metals, and compare data for filtered and unfiltered samples to determine which data to use in the risk assessment; or (2) explain the impact of using filtered metals data on the results of the risk assessment. Option 1 is more favorable but may be impractical at this point in the process.

Response: The DOE agrees that the use of filtered versus unfiltered data is an issue that must be addressed in RI/FS investigations and public health risk assessments. Unfiltered and filtered metals samples were collected from the majority of the FEMP background monitoring wells during the OU5 groundwater monitoring Snapshot Program.

Action:

The Background report will be revised at a later date when unfiltered and filtered metals data from the Snapshot Program have been received and validated. When validated, the OU5 Snapshot data will be available for future risk assessments prepared for the FEMP. Also, as suggested by the reviewer in Option 2, the DOE will comment in each RI Report (except for the OU4 RI, which has already been submitted to EPA) on the impact of using filtered background metals data on the results of risk assessments.

Comment: Section 9 presents the conclusions of the background calculations and summarizes Section 4.0. One problem with the scheme outlined in Section 4.0 results from several parameters having upper tolerance limits that exceed health-based standards, particularly regarding applicable regulations like maximum contaminant levels (MCL) and corresponding action levels for copper and lead. Affected parameters include the following:

- Cadmium and mercury in all three water sources listed in Table 21
- Arsenic, chromium, lead, and nickel in both aquifers
- Beryllium in the glacial overburden
- Antimony and nitrate in the Great Miami Aguifer.

When using data to decide which contaminants should be considered chemicals of concern for the risk assessment, FEMP should lower the tolerance limits for these analytes to the MCL. In any event, all risk assessments should include separate, parallel calculations for the risk posed by relevant background concentrations. The calculations should be drawn from the data base used in this background study and should use the same exposure point concentrations, water sources (aguifers and streams), and so on as the risk assessment itself. In addition, the calculations should include all background chemicals, whether they are used in the main risk assessment or not. This type of information will be useful to risk managers when making decisions.

Response: In nearly every case, the arithmetic mean, geometric mean, or median values of background concentrations for metals were below respective maximum concentration limits (MCLs/MCLGs). The only exception that was evident was the median value for cadmium for the Great Miami River (6 μ g/L), which exceeds the MCL of 5 μ g/L. Because of the high variability of concentrations in background levels, the standard deviation of sample populations is high, and the UCLs and UTLs are subsequently high. The UCLs and UTLs were calculated using data collected during RI/FS studies and procedures recommended by the U.S. EPA.

The DOE does not agree that "the FEMP should lower the tolerance limits for analytes to the MCLs." A comparison to MCLs is an important consideration in the selection of constituents of concern (CPCs). As discussed in the attached Guidance, Selected Exposure Routes and Contaminants of Concern by Risk-Based Screening, a comparison to background and a comparison to MCLs are among the many factors that should be considered in the selection of CPCs. Neither factor should be applied independently of the other. Rather all factors listed in the Guidance should be considered in an effort to properly select CPCs.

The DOE agrees that baseline risk assessments should include an assessment of background concentrations.

Action:

A risk assessment of background concentrations will be included in all risk assessments.

Technical Guidance Manual
Risk Assessment

Selecting Exposure Routes and Contaminants of Concern by Risk-Based Screening

EPA Contact: Dr. Roy L. Smith

EPA Region III

Hazardous Waste Management Division Office of Superfund Programs January 1993

Human health risk assessment includes effort-intensive steps which require many detailed calculations by experts. Most baseline risk assessments are dominated by a few chemicals and a few routes of exposure. Effort expended on minor contaminants and exposure routes, i.e., those which do not influence overall risk, is essentially wasted. This guidance is intended to identify and focus on dominant contaminants of concern and exposure routes at the earliest feasible point in the baseline risk assessment. Use of these methods will decrease effort and time spent assessing risk, without loss of protectiveness. This guidance is not intended for other risk assessment activities, such as determining preliminary remediation goals.

SELECTING CONTAMINANTS AND EXPOSURE ROUTES OF CONCERN

Most samples from hazardous waste sites are analyzed for 103 target compounds and analytes recommended by the EPA Superfund program: Semi-volatile analysis can detect additional tentatively identified compounds not on the target lists. Special analytical services procedures, if used, may find still more contaminants. The combined number of contaminants detected at a site sometimes exceeds one hundred.

While EPA considers it necessary to gather information on many contaminants, very little of this data actually influences the overall quantitative assessment of health risk. For most sites, baseline risk assessments are dominated by a few contaminants and a few routes of exposure. The remaining tens, or hundreds, of detected contaminants have a minimal influence on total risk. This small impact is lost by rounding. Entire environmental media may contain not a single contaminant at a concentration which could adversely affect public health. Quantitative risk calculations using data from such *risk-free* media have no effect on the overall risk estimate for the site.

The EPA baseline risk assessment process at several points requires careful data evaluation by scientific

experts. These evaluations, which are contaminant-specific, include: (1) statistical comparisons between site-related and background samples, (2) special handling of undetected contaminants, (3) calculation of toxicity equivalence, (4) evaluation of frequency of detection, and (5) comparison with ARARs. Because overall risk is usually driven by a few contaminants and exposure routes, effort spent in detailed evaluation of minor contaminants and routes of exposure is essentially wasted. For some sites, this wasted effort exceeds 90% of the total.

The baseline risk assessment process can be made more efficient by focusing on dominant contaminants and routes of exposure at the earliest feasible stage. The mechanisms recommended for this are (1) a reordering of the process of eliminating contaminants and routes of exposure, and (2) use of a risk-based concentration screen. Appropriately used, this process can dramatically reduce the effort of risk assessment, while not changing the result significantly.

EXISTING GUIDANCE

Chapter 5 of RAGS IA* (Risk Assessment Guidance for Superfund, Volume I, Human Health Evaluation Manual (Pan A); EPA, 1989) provides a detailed procedure for evaluating data for a baseline risk assessment. This

- 4832

procedure includes steps by which the risk assessor selects contaminants of concern in each exposure medium. These steps are summarized in Table 1.

There are two major limitations to the RAGS procedure. First, the eliminating step (a concentration toxicity screen) comes late in the process. Many of the preceding steps (e.g., evaluation of quantitation limits, comparison with background, calculation of toxicity equivalence, and evaluation of frequency of detection) are contaminant- and medium-specific. They require the sustained attention of an expert, and cannot be automated. If the contaminant is eliminated, this work is wasted.

The second limitation is that the concentration toxicity screen compares only relative risk among contaminants in the same medium. While very efficient at selecting dominant contaminants in each medium, this method does not evaluate significance of total risk for the medium. Thus, the concentration toxicity screen can eliminate contaminants, but not routes of exposure.

RECOMMENDED METHODOLOGY

's guidance makes two changes intended to remove ...e limitations in existing guidance. These recommendations are intended for baseline risk assessments.

1. Re-ordering of steps. The eliminating screen is moved forward in the data evaluation process to a point immediately following data quality evaluation. The new process is shown in Table 2. Effort-intensive steps such as evaluation of quantitation limits and comparison with background now follow the eliminating screen. The many are divided into four categories: data quality mustion, initial data set reduction, re-inclusion of special cases, and optional final data set reduction.

The date quality evaluation steps (evaluating appropriateness of methods and qualifiers, significance of blank contamination, and need for special analyses) should be done as described in RAGS IA, Chapter 5. Next, the risk assessor should consult with the RPM to discuss the use of the risk-beard concentration table (described in item [2] below) as a screening mechanism. With the RPM's approval, the risk assessor should reduce the data set and document the rationale for eliminating contaminants and routes of exposure from further analysis.

After the Initial data set reduction, the risk assessor and RPM should consider re-including specific contaminants on the basis of historical data, toxicity, mobility, persistence, bloaccumulation, special exposure

routes, special treatability problems, or exceedance of ARARs. These activities should proceed as described in Section 5.9 of RAGS IA.

Finally, optional further reductions in the data set may be justified, based on the status of a contaminant as an essential nutrient, low frequency of detection, or no statistical difference between site and background levels. These evaluations, the most complicated and contaminant-specific, are saved for last.

Screening by risk-based concentrations. screening method is changed from the relative concentration toxicity screen of RAGS IA to an absolute comparison of risk. This is done by means of a table of risk-based concentrations (Appendix I). This table contains levels of nearly 600 contaminants in air, drinking water, fish tissue, and soil, which correspond to a systemic hazard quotient of 0.1 or a lifetime cancer risk of 10°. The risk-based concentrations were developed using protective default exposure scanarios suggested by EPA (1991) and the best available reference doses and carcinogenic potency slopes (see the table for sources), and represent relatively protective environmental concentrations at which EPA would typically not take action.

The risk-based concentration screen is used as follows:

- (a) The risk assessor extracts the maximum concentration of each substance detected in each medium.
- (b) If the maximum concentration exceeds the riskbased concentration for that medium, he contaminant is retained for risk assessment, for all routes of exposure involving that medium. Otherwise the contaminant is dropped for that medium.
- (c) If a specific contaminant does not exceed its riskbased concentration for any medium, the contaminant is dropped from the risk assessment.
- (d) If no contaminant in a specific medium exceeds its risk-based concentration, the medium is dropped from the risk assessment.
- (e) All contaminants and exposure routes which are dropped are kept on a sub-list and considered for re-inclusion, based on special properties.
- (f) If the risk assessor wants to include a route of exposure not covered in the risk-based concentration table, the equations provided in Appendix I can serve as the basis for new risk-

based concentrations. Similarly, the risk assessor can use the same equations to calculate alternate risk levels (i.e., other than a systemic hazard quotient of 0.1 and lifetime cancer risk of 10°) to be the basis for screening.

SUMMARY

The process by which contaminants and exposure routes are selected in quantitative risk assessment can be made less effort-intensive by two simple changes. First, high-effort steps should be postponed until later in the selection process, because performing these operations on trivial contaminants and exposure routes is pointless. Second, changing from a relative concentration toxicity screen to an absolute risk-based concentration screen improves the risk assessor's ability to focus on dominant contaminants and exposure routes at an earlier stage.

- C. Consider re-including eliminated chemicals and routes, based on:
 - 8. Historical Information
 - 9. Exceptional toxicity, mobility, persistence, or bioaccumulation
 - 10. Special exposure routes
 - 11. Special treatability problems
 - 12. ARARS exceedance
 - 13. Toxicity equivalence of chemical class (e.g., CDD/CDFs. PAHs)
- D. Make further specific reductions in data set (optional)
 - 14. Evaluate essentiality
 - 15. Evaluate frequency of detection
 - 16. Compare site samples to background

Appendix I: EPA Region III Risk-Based Concentration Table Background Information

The risk-based concentrations were calculated as follows:

GENERAL: Separate risk-based concentrations were calculated for carcinogenic and non-carcinogenic effects of each compound for each pathway. The concentration in the table is the lower of the two, rounded to two significant figures. For non-carcinogenic effects, the averaging time equals the exposure duration, so the exposure duration term has been used for both. The following terms were used in the calculations:

General: Oral carcinogenic slope factor (mg/kg/d)⁻¹: SF, Inhaled carcinogenic slope factor (mg/kg/d)⁻¹: SF. Oral reference dose (mg/kg/d): RID. Inhaled reference dose (mg/kg/d): RfD. Target cancer risk: TR Target hazard quotient: THO BW. Body weight, adult (kg): Body weight, child age 1-6 (kg): BW, Averaging time (years of life): AT IR, Air breathed (m³/d): IR, Drinking water ingestion (L/d): IR. Fish ingestion (g/d): Soil ingestion - age adjusted (mg/d) IRS_ IRS. Soil ingestion - age 1-6 (mg/d): Soil ingestion - adult (mg/d): IRS. Residential: Exposure frequency (d/y): EF. ED. Exposure duration (y): Volatilization factor (L/m³): VF

The priority among sources of toxicological constants was as follows: (1) IRIS, (2) HEAST, (3) HEAST alternative method, (4) ECAO-Cincinnati, (5) other EPA documents, (6) withdrawn from IRIS, and (7) withdrawn from HEAST. Each source was used only if numbers from higher-priority sources were unavailable.

- 1. Residential water use $(\mu g/L)$. Volatilization terms were calculated only for compounds with "y" in the "Volatile" column. Compounds having a Henry's Law constant greater-than 10^5 were considered volatile. The list may be incomplete, but is unlikely to include false positives. The equations and the volatilization factor (VF, above) were obtained from the draft RAGS IB. Oral potency slopes and reference doses were used for both oral and inhaled exposures for volatile compounds lacking inhalation values. Inhaled potency slopes were substituted for unavailable oral potency slopes only for volatile compounds; inhaled RfDs were substituted for unavailable oral RfDs for both volatile and non-volatile compounds.
